

### Abstract of the Disclosure

A preferred embodiment safety device for use with an upright structure includes an elongate member, a connecting member, a securing member, and a lifeline. The connecting member is operatively connected to the elongate member proximate a first end of the elongate member. The connecting member extends outward from the elongate member and is configured and arranged to engage the upright structure. The securing member is operatively connected to the elongate member proximate a second end of the elongate member. The securing member is configured and arranged to extend around a portion of an anchor member. The connecting member and the securing member anchor the elongate member thereby providing an anchorage point. The lifeline is operatively connected to the elongate member, wherein the lifeline provides fall protection proximate the upright structure when the elongate member is anchored.
